4

Motivation

- SubBytes is a nonlinear transformation among AES transformations.

- Current fault detection schemes:
  - Dependent on the way the S-box is constructed.
  - May not be used for all the implementations of the S-box.

- The presented fault detection scheme:
  - Independent of the type of the implementation of the S-box.
  - Can be applied to both look-up table and composite field realizations of the S-box.

Multiplication: A Previous Approach

- The 8-bit input of the multiplicative inversion is multiplied by the 8-bit output and the n-bit result of the multiplication is compared with the n-bit actual result.
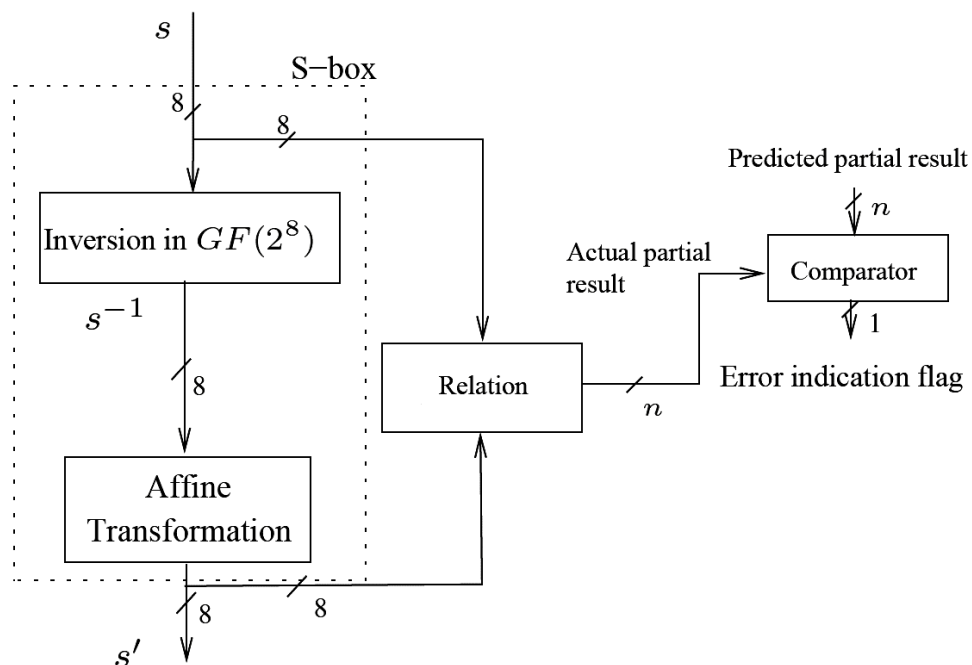

Multiplication: A Previous Approach

- Based on the relation of the input and output of the multiplicative inversion.

- The multiplication approach is costly
  - 64 ANDs and 84 XORs (after sub-expression sharing)
  - Approximately 93% area overhead for a typical composite field realization

- Previous schemes suggest using the two least significant bits of the result for comparison.

- We suggest using the most and least significant bits resulting in 7% area overhead reduction.

Multiplication: A Previous Approach

- Disadvantages:

    - Fault detection of the multiplicative inversion in the S-box/inverse S-box.

    - Does not include the affine/inverse affine transformation.

    - Therefore, it is not suitable whenever the output of the multiplicative inversion is not available.

The Proposed Structure-Independent (Scheme 1)

– Independent of the type of realization of the S-box/inverse S-box
– Takes the affine/inverse affine transformation into account
– Suitable for look-up table as well as composite field realizations of the S-box/inverse S-box

- Theorem:

Let $S = s_7\alpha^7 + s_6\alpha^6 + s_5\alpha^5 + s_4\alpha^4 + s_3\alpha^3 + s_2\alpha^2 + s_1\alpha + s_0$ and

$S' = s_7'\alpha^7 + s_6'\alpha^6 + s_5'\alpha^5 + s_4'\alpha^4 + s_3'\alpha^3 + s_2'\alpha^2 + s_1'\alpha + s_0'$ be the input and the output of the S-box, respectively. Then we have the following relation between the input and the output of the S-box:

$$Ms' + m = 1$$

Where, matrix **M** and vector **m** are functions of the input of the S-box, **s'** is the column vector of the coordinates of the output and vector **1**=[1 0 0 0 0 0 0 0]^T .

4th Workshop on Fault Diagnosis and Tolerance in Cryptography – FDTC 2007

10

The Proposed Structure-Independent (Scheme 2)

– Although the structure-independent scheme detects all errors in the output of the S-box, its implementation is costly (64 ANDs and 111 XORs after sub-expression sharing).

– To reduce the cost, we obtain a signature (parity) of the result.

4th Workshop on Fault Diagnosis and Tolerance in Cryptography – FDTC 2007

11

The Proposed Structure-Independent (Scheme 2)

- Single-bit parity can be used and compared with one for detecting any combination of odd number of erroneous bits at the result as follows

$$P_{(MS'+m)} = P_b = 1$$

- This needs 20 XORs and 8 ANDs with the delay of 4 XORs and one AND.

- Using an OR tree, the error indication flags of 16 S-boxes are ORed to obtain the flag of the SubBytes transformations.

12

Simulation Results

- Our simulations are based on considering the S-box and its fault detection circuit by injecting all possible errors to the output.

- For the 255 inputs, 255 possible erroneous outputs for both stuck at zero and one are evaluated.

- Our simulations show that the error coverage for one S-box is approximately 50%.

- If we consider 16 S-boxes in SubBytes, the cases in which any of the S-boxes detect an error are among the error detection cases resulting in the error coverage of 99.998%.

13

FPGA Implementations

- As a typical implementation, we have implemented the look-up table realization of the S-box in the AES encryption.

- XILINX ISE 8.2 and Virtex 5 family is used.

- We use pipelined distributed RAMs for implementing the SubBytes transformation.

Scheme	Operation	SRs, SLUTs	Slice overhead	Freq. (Mhz)	Thro'put (Gbps)	Efficiency (Mbps/slice)
AES with SubBytes using Pipelined Distributed RAMs (xc5vlx30-3)	Original AES	2560, 8490	0% SR 0% SLUT	482.998	61.8	29.1
	Proposed scheme for SubBytes,ShiftRows	2560, 9806	0% SR 15% SLUT	482.998	61.8	25.2

14

Comparison

- We have implemented the proposed scheme for SubBytes used the scheme in **[Bertoni et al., 2003]** for other transformations in the AES encryption.

- Our scheme and the one that uses 512*9 memory cells for the S-box are compared as follows

Operation	Device	SRs, SLUTs	Slice overhead	Freq. (Mhz)	Thro'put (Gbps)	Efficiency (Mbps/slice)
scheme in [1] using 512×9 ROMs for S-box	xc5vlx85-3	3600, 16138	40% SR 90% SLUT	478.286	61.2	15.2
Proposed scheme for SubBytes scheme in [1] for others	xc5vlx30-3	2560, 10559	0% SR 24% SLUT	482.998	61.8	23.4

15

Conclusions

- In this paper, a structure-independent fault detection scheme for the AES SubBytes transformation has been presented.

- This scheme can also be used for the fault detection of InvSubBytes transformation by swapping the inputs and the outputs.

- The presented scheme detects most of the random faults in the SubBytes and ShiftRows transformations, independent of the location of the faults.

- Finally, the area overhead of our structure-independent scheme is reasonable for resource constrained hardware implementations of the AES.
